Abstract

The main aim was to investigate functional predictors of driving ability in older adults. The principal focus was on cognitive predictors, but visual and physical function measures were also included. The cognitive assessments reflected domains identified as most relevant to driving outcomes, including visual attention, processing speed, and general cognitive functioning. The specific cognitive tests included the Useful Field of View Test™ (UFOV™), which is notable for its consistent relationship with a broad range of driving outcomes; and Inspection Time (IT) and ProPerVis, assessments of processing speed and crowding across the visual field, respectively, which have not previously been investigated in relation to driving outcomes but have potential as screening tests. A secondary aim of the thesis was to investigate methodological issues concerning use of driving simulators.

Five studies formed a sequential program of research. Study 1 examined factors contributing to performance on the UFOV™; although the UFOV™ has been extensively used in past research, its psychometric properties are not yet well understood. The results from Study 1 showed that UFOV™ Subtest 1 primarily reflected low-level visual function; UFOV™ Subtest 2 reflected change detection, processing speed (as assessed by IT), and general cognitive function; and UFOV™ Subtest 3 reflected crowding (as assessed by ProPerVis), processing speed (as assessed by IT), contrast sensitivity, and general cognitive function. These results suggested that IT and Crowding may be useful in predicting driving performance, based on their importance for UFOV™ Subtests 2 and 3, which have been consistently linked to important driving outcomes. Studies 2, 3 and 4 investigated methodological issues related to driving simulators, including simulator sickness, validity, reliability, and usability. The results from Study 2, which investigated risk factors for simulator sickness, showed that older adults in general are a high-risk group, as are females and those with a history of motion sickness. Studies 3 and 4 used a variety of methods to show that the simulator demonstrated reliability, face validity, content validity, and convergent validity, and was perceived by participants as providing an acceptable method of assessing driving skills.

Study 5 investigated functional predictors (cognitive, visual, and physical) of simulated driving performance on two tasks: a Brake Reaction Time (RT) task and a Traffic Participation Task. The results from Study 5 showed small but significant correlations between cognitive test performance (IT, Crowding, and UFOV™ Subtest 2) and Brake RT. For the Traffic Task, only Crowding was significantly correlated with driving performance. Physical activity and visual function were not associated with driving performance. These results have implications for current assessment procedures. They suggest that visual function measures are not generally useful for determining fitness-to-drive, a conclusion that has important implications for practices at present widespread in many jurisdictions responsible for driver licensing. Regarding the cognitive measures, it is suggested that the IT and Crowding measures may be useful as screening measures for older drivers, especially those who are most at-risk. Further research with a broader range of participants would be needed to establish appropriate test cut-points. Limitations and further implications of the results are discussed.

Signed Statement

I certify that this work, except where specified in the text, contains no material which has been accepted for the award of any other degree or diploma in my name in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint award of this degree.

I give consent to this copy of my thesis when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

Acknowledgements

I would like to thank my supervisors, Emeritus Professor Ted Nettelbeck and Professor Nick Burns. Your advice and support has been invaluable. Ted suggested the original idea for the project and provided me with encouragement and expert guidance throughout my candidature. I am grateful to Nick for his technical assistance and novel approach to statistical analysis. I am privileged to have had you both as advisors and mentors.

I gratefully acknowledge the support of Duncan Ward and the staff at Sydac Pty Ltd who donated their time to the development of the custom driving simulator used in this thesis and provided me with office space, support, and materials during the early stages of the project. Your generosity and expertise were sincerely appreciated.

I also acknowledge the staff at SimWorx for their advice and technical assistance during the latter stages of the project.

Thank you to my family, friends, and colleagues for your support throughout my candidature. The journey has been challenging at times but your encouragement and interest kept me motivated to achieve my goals.

Most of all, thank you to all of the participants who volunteered their time. I am particularly thankful to those participants who assisted in recruiting others to the project. I am grateful to have met many kind, generous and interesting people during this process. This thesis would not have been possible without your enthusiastic participation.
