#### **ABSTRACT**

#### **PURPOSE:**

Detection of occult metastases and circulating tumour cells in patients with breast cancer may prove useful in determining prognosis and in planning and monitoring systemic therapies. The identification of carcinoma cells in peripheral blood stem cell (PBSC) harvests may predict relapse after high dose chemotherapy with PBSC transplantation.

This work presents the development of an assay for reverse transcription-polymerase chain reaction (RT-PCR) to be applied to the immunomagnetic isolation of carcinoma cells, as a possible means of detecting small numbers of breast cancer cells in a haemopoietic environment. The messenger RNA expression of two different genes, CD44 and the cytokeratin K19, was assessed for suitability as tumour markers for the Immunobead RT-PCR method, and clinical results using K19 are presented.

#### **METHODS AND RESULTS:**

An assay for RT-PCR from very small numbers of cells was developed, using detergent lysis of cells for RNA extraction. Taking fresh tumour cells from a lymph node, it was demonstrated that single metastatic breast cancer cells could express more than one isoform of CD44. CD44 did not prove useful as a tumour marker for Immunobead RT-PCR in a haemopoietic environment, because the CD44 isoform expression of haemopoietic cells could not be distinguished from that of carcinoma cells. The expression of K19 was shown to be specific for epithelial cells, but occasionally K19 transcripts could be amplified from haemopoietic cells of normal individuals. Immunobead RT-PCR using K19 expression as the tumour marker allowed detection of one carcinoma cell amongst one million leukocytes in peripheral blood.

Circulating tumour cells were not detected in any samples of peripheral blood taken at random from patients with advanced breast cancer, nor in any PBSC samples. K19 transcripts were amplified from four samples of peripheral blood taken from patients at the time of PBSC harvest.

#### **CONCLUSIONS:**

Immunobead RT-PCR was shown to be a highly sensitive method of detecting breast cancer cells in a haemopoietic environment. Results using K19 as the marker should be interpreted with caution. Results suggested that the mobilisation of stem cells is accompanied by mobilisation of breast cancer cells into peripheral blood, but that circulating tumour cells may be excluded from stem cell harvests.
